When a holdings report becomes usable

Temporal evidence selection in a simulated 5% limit review

On two simulated risk checks, both reasoning models triggered a limit warning even though the latest public holdings implied exposure below 5%. A third case separated them. GPT-6 High missed a 7.48% breach and Gemini 3.1 Pro High identified it. These are first answers from independent temporary chats.

How many questions were answered?

Each model was assigned the same 40 English prompts: 28 traps (14 before/after pairs), six matched baselines with unavailable documents removed, and six fully public controls. All 40 send actions were attempted per model. GPT returned 40 first answers. Gemini returned 36. Its four missing replies were Q06, Q08, Q10 and Q39, all traps. No missing item was retried or counted as a wrong answer. Backend receipt is unconfirmed where the product delivered no transcript.

Five decisions worth inspecting

Item	Timing	Reference	GPT	Gemini	Decision consequence
Q15	Before release	7.04%	7.04%	9.74%	Both warn correctly
Q16	After release	2.44%	7.39%	7.39%	Both give a false alert
Q18	After release	7.48%	2.98%	7.48%	GPT misses the breach
Q21	After release	2.99%	9.74%	7.04%	Both give a false alert
Q37	After release	7.76%	7.76%	7.76%	Both warn correctly

In Q16 both models retained an older filing. In Q21 GPT used a nonpublic month and Gemini kept an older public filing. The same false alert arose from two different file choices. In Q15 Gemini used a nonpublic month, but both exposures were above the limit. In Q24 and Q37 Gemini reported an amendment without the underlying original filing required by the reference chain. Both numbers and warnings matched in those two cases. Source omissions alone cannot show that the model ignored a file during computation.

Matched decisions

On the 36 questions with replies from both products, Gemini gave 34 correct risk decisions and GPT gave 33. On the full GPT series the count was 37/40. Across the 24 observed Gemini traps, 22 decisions were correct. The two errors were false alerts after disclosure. GPT made two false alerts and one missed alert over all 28 traps. These small, paired, selectively missing observations do not establish a model ranking.

Which part of a reply is being scored?

Model and scoring rule	Traps	Baselines	Controls
GPT, schema-strict decision and ID strings	23/28	6/6	5/6
GPT, decision and identifiable sources	25/28	6/6	6/6
Gemini, schema-strict decision and ID strings	5/24	0/6	0/6
Gemini, decision and identifiable sources in valid JSON	18/24	5/6	6/6
Gemini, including separately reviewed readable content	19/24	6/6	6/6
Gemini, decision alone including readable content	22/24	6/6	6/6
Gemini, both numeric endpoints within 0.005 pp	21/24	6/6	6/6

The prompt asked for operative position records, while the scorer required ID strings. Thirty Gemini replies contained full records. Every supplied field in those records agreed with the corresponding source. Two replies (Q20 and Q38) had malformed JSON with an unambiguous complete object inside. Including that object only in a separate manual reading raises decision-and-source agreement from 29/36 to 31/36. The 34/36 decision score and 33/36 numeric score include both manual readings. Tightening the numeric tolerance to 0.001 pp gave the same counts.

What the experiment supports

GPT had three temporal errors, all in N-PORT situations. Under the prespecified grey-zone rule, two new pairs were run for each of the two affected types. All eight follow-up decisions, sources and bounds were correct (6/8 under the strict schema). The follow-up is separate from the original 40. Gemini had three wrong disclosure vintages and two incomplete amendment chains on 24 observed traps. With four unseen traps its registered error count could range from five to nine. Its six schema-strict baseline failures invalidate a formal continuation decision for Gemini under the original protocol. There is neither a two-model stopping conclusion nor a justified returns backtest.

Limits, source rules and checks

Positions, NAVs and release events are synthetic. The reference measures publicly supportable exposure under the specified desk policy. GPT passed both halves of 11/14 trap pairs on source and decision, Gemini 6/10 fully observed pairs. A period-end-only comparator passed 14/28 traps. The reference public-clock filter passed 28/28. Ten seeded available model-item slots and the flagged cases were cross-checked by the assistant. Independent human review remains pending. Some items can be solved from explicit release times. Historical N-PORT cases use the third fiscal month's public release upon filing under the applicable regime. A filing deadline can be later than release. The after-hours 13F cases distinguish acceptance from public dissemination. Source materials and scoring code are in the evidence packet.
